

Answers

1. A straight lerp on an object's scale might not always provide a perceptually smooth result.

Answer: True

2. A loglerp uses a logarithmic transform of the inputs before applying the linear interpolation.

Answer: True

3. Interpolating the area of an object can be achieved by taking the squared property of size into account.

Answer: True

4. Loglerp is a suitable method for all interpolation tasks.

Answer: False

5. Describe the visual difference when scaling an object using a linear lerp vs. a loglerp.

Answer: Generally you mostly just want to capture that the scale seemingly starts quickly, and then slows down. This is almost like an easeOut function. Using logLerp, the scaling appears more perceptually linear and smoother.
